

This Dissertation

entitled

Search for lepton flavor violating decays of the Higgs boson

typeset with NDdiss2 $\epsilon$  v3.0 (2005/07/27) on November 25, 2017 for

Fanbo Meng

This L<sup>A</sup>T<sub>E</sub>X 2 $\epsilon$  classfile conforms to the University of Notre Dame style guidelines established in Spring 2004. However it is still possible to generate a non-conformant document if the instructions in the class file documentation are not followed!

Be sure to refer to the published Graduate School guidelines at <http://graduateschool.nd.edu> as well. Those guidelines override everything mentioned about formatting in the documentation for this NDdiss2 $\epsilon$  class file.

It is YOUR responsibility to ensure that the Chapter titles and Table caption titles are put in CAPS LETTERS. This classfile does *NOT* do that!

*This page can be disabled by specifying the “noinfo” option to the class invocation.*  
(i.e., `\documentclass[... ,noinfo]{nddiss2e}` )

**This page is *NOT* part of the dissertation/thesis, but  
MUST be turned in to the proofreader(s) or the  
reviewer(s)!**

Search for lepton flavor violating decays of the Higgs boson

Abstract

by

Fanbo Meng

this going to put with the abstract, a summary of the whole analysis

NEW DEDICATION NAME

To be written

## CONTENTS

## FIGURES

## TABLES

## PREFACE

probably I will write some preface, but it depends  $H \rightarrow \mu\tau_h$

## ACKNOWLEDGMENTS

this part is going to be filled with acknowledge

## CHAPTER 1

### Introduction

1.1 Pre-LHC era on lepton Flavor violation(LFV) search and results

1.2 Overview of CMS Run1 and Run2 direct search on LFV

## CHAPTER 2

### Theory

#### 2.1 Standard model

#### 2.2 LFV in beyond standard model theories

## CHAPTER 3

### LHC and CMS experiment

#### 3.1 LHC accelerator

#### 3.2 CMS experiment

##### 3.2.1 Tracker

##### 3.2.2 ECAL

##### 3.2.3 HCAL

##### 3.2.4 Muon System

##### 3.2.5 Trigger

probably I have to put something there

##### 3.2.5.1 Level 1 Trigger

probably I have to put something there2

##### 3.2.5.2 High Level Trigger

## CHAPTER 4

### Datasets

4.1 Datasets used in LFV analysis

4.2 Event reconstruction

4.3 Event simulation

## CHAPTER 5

LFV analysis background estimation

## CHAPTER 6

### LFV event selection

For both the 8TeV analysis  $H \rightarrow e\tau_h$  channel and 13TeV analysis  $H \rightarrow \mu\tau_h$ , events are selected in several steps. The loose(base) selection on the different IDs, energy, geometry parameters of the analysis related objects and so on are applied. For both  $H \rightarrow e\tau_h$  and  $H \rightarrow \mu\tau_h$  analysis channel, a following cut-based analyses are applied. For  $H \rightarrow \mu\tau_h$ , a multivariate analysis with Boosted decision tree (BDT) is exploited to provide more sensitive results.

#### 6.1 $H \rightarrow \mu\tau_h$

##### 6.1.1 Loose selection

In  $H \rightarrow \mu\tau_h$  events, tau leptons from signal events decay hadronically and most of the time,  $\mu$  candidates pass all the way to the muon detector. SM higgs is much heavier than the LFV decay products  $\mu$  and  $\tau$ , so  $\mu$  and  $\tau$  are expected to have high  $P_T$ . Since the decay products are boosted, a cut on the  $\Delta R > 0.3$  is applied, in which  $\Delta R$  is defined as  $\Delta R = \sqrt{(\Delta\phi)^2 + (\Delta\eta)^2}$ . Higgs particle has no charge, so  $\mu$  and  $\tau$  candidates are required to have opposite charges. Further, the events with additional  $\mu$  and  $\tau$  that pass a loose selection, the events with jets that are identified by the combined secondary vertex(CSVv2) b-tagging algorithm

TABLE 6.1

BCDEF.

ICHEP mediumID description	Technical description
Loose muon ID	PFLoose Muon
Fraction of valid tracker hits	$> 0.49$
1.Good Global muon	Global muon
	Normalized global-track $\chi^2 < 3$
	Tracker-Standalone position match $< 12$
	kick finder $< 20$
	Segment compatibility $> 0.303$
2. Tight segment compatibility	Segment compatibility $> 0.451$

Hadronic taus are required to have  $P_T > 30\text{GeV}$ ,  $|\eta| < 2.3$ , pass old tau decay mode finding(chapter 4.2) and an MVA based tight tau isolation ID(chapter 4.2) and tau discriminators against other objects. These discriminators are very loose MVA based rejection against electrons and the cut-based tight rejection against muons.

The events in the analysis are divided into four categories based on the number of jets in the events. In 2-jets categories, it is furthered divided into 2 categories, 2-jet gluon gluon fusion higgs production(ggH) category and 2-jet VBF category based on the value of 2 jets invariant mass( $M_{jj}$ ) . In the 0-jet category, the

TABLE 6.2

Muon ID used in the analysis, for the LHC data 2016, running period G and H, also the monte Carlo samples.

Standard mediumID description	Technical description
Loose muon ID	PFLoose Muon
Fraction of valid tracker hits	$> 0.8$
1. Good Global muon	Global muon
	Normalized global-track $\chi^2 < 3$
	Tracker-Standalone position match $< 12$
	kick finder $< 20$
	Segment compatibility $> 0.303$
2. Tight segment compatibility	Segment compatibility $> 0.451$

signal mainly comes from ggH. In 1-jet category, the dominant signal production mode is also ggH, but with a boosted jet associated with the production, some of the VBF higgs signal also shows up in this category. In the 2-jet ggH category, signal events mainly comes from ggH and in 2-jet VBF, VBF production dominates the production mode. In the following is a more detailed listing of the selection condition in each categories.

**0-jet:** No events have jets pass the loose PF ID and with jet  $P_T > 30 \text{ GeV}$ ,  $|\eta| < 4.7$ .

**1-jet:** The events with one jet passes loose PF ID and jet  $P_T > 30 \text{ GeV}$ ,  $|\eta| < 4.7$ .

**2-jets GG:** The events have two jets pass loose PF ID and with jet  $P_T > 30 \text{ GeV}$  and  $|\eta| < 4.7$ , also require an invariant mass of the two jets,  $M_{jj} < 550 \text{ GeV}$ .

**2 jets VBF:** The events have two jets pass loose PF ID and with jet  $P_T > 30 \text{ GeV}$  and  $|\eta| < 4.7$ , also require  $M_{jj} > 550 \text{ GeV}$ .

The threshold on  $M_{jj}$  has been optimized to give the best expected limits.

### 6.1.2 Cut-based analysis

With the loose selection, including the categorization, a further cut-based selection strategy is applied. The selected variables that can help distinguish signal from background used in this analysis are the following ones:  $P_T^\mu$ ,  $P_T^\tau$ ,  $M_T(\tau_h)$ . The lepton  $P_T$  variables are very powerful background discriminant variables, but it will also cause the problem that signal picks under the background. Leptons from signal process incline to have higher  $P_T$  values, by cutting tighter on the lepton  $P_T$ , more background events can be removed. However this will also reshape some of the backgrounds, making them peak closer under signal so as making the

signal discovery processes affected more by the background statistics fluctuation. In the  $H \rightarrow e\tau_h$  analysis, the effect of cutting hard on lepton  $P_T$  will be shown. So in  $H \rightarrow \mu\tau_h$  search, lepton  $P_T$  variables are kept at loose values and tune on other variables to achieve better signal significance.

The tuning process is done only with Monte Carlo samples to not double use data. The final results are extract with data, so the double use of data may cause some biases on the results. The fake background estimated with full data driven method, is replaced with the semi data driven estimation in tuning. In  $M_T(\tau_h)$  channel, the variables tuned are  $M_{jj}$  and  $M_T(\tau_h)$ . The cuts have been optimized to have the most stringent expected limits with the Asimov dataset. If the same cut, but close values of the cut give same expected limits, then chose the loose cut value to have most stringent expected limits and have as much statistics as possible. Examples of obtaining the limits are shown in Fig. ??, the  $M_T(\tau_h)$  for the different categories and Fig. ?? for the optimization of  $M_{jj}$  in 2-jets categories.

### 6.1.3 Multivariate analysis

A Boost decision trees(BDT) method is chosen as the multivariate analysis method used in  $H \rightarrow \mu\tau_h$  search. It provides greater sensitivity compared with the cut-based analysis. BDT method takes in two set of datasets, signal and background and a selected set of input variables. The input variables are the ones that show distinguishing power between signal and background. The training output is a weight file, which contains a list of weights to indicate in percentage how likely an event is signal like with a give set of input variable values from that event. A more detail description of the BDT method is available in section ?. In this analysis, signal and background events are required to pass the lose selection

(a) 0 jet

(b) 1 jet

(c) 2 jets, gg-enriched

(d) 2 jets, VBF-enriched

Figure 6.1. Expected limits based on an Asimov dataset as a function of  $M_T(\tau, MET)$  for the different categories.

Figure 6.2. Expected limits based on an Asimov dataset as a function of  $M_{jj}$  for the 2 jet categories.

criteria. All of the categories are combined. The signal events from gluon gluon fusion and vector boson fusion higgs production mode are mix by the weight with their respective production cross section. The background sample used in the training is fake background in the like sign region(Region II as in table \*\*), which is orthogonal to the signal region and avoid double use the data. The distribution of input variables in the BDT training is the shown in Fig. ??.

- Transverse mass between the  $\tau_h$  and  $E_T^{miss}$ ,  $M_T(\tau_h)m$ .
- Missing transverse energy,  $E_T^{miss}$ .
- Pseudorapidity difference between the muon and the  $\tau_h$  candidate,  $\Delta\eta(\tau_h)$ .
- Azimutal angle between the muon and the  $\tau_h$ ,  $\Delta\phi(\tau_h)$ .
- Azimutal angle between the  $\tau_h$  and the  $E_T^{miss}$ ,  $\Delta\phi(\tau_h, E_T^{miss})$ .
- Collinear mass,  $M_{col}$ .

- Muon .
- $\tau_h$  .
